

The Bearded Vulture

The Bearded Vulture lives in mountainous terrain, hunting among rocks, meadows, and high-altitude lakes throughout the world. It is currently endangered throughout Europe, but seems fairly healthy in Asian environments.

The Brown Bear

The Brown Bear, or grizzly, lives in northern Europe and North America. They are omnivores who feed mostly on plants, roots, and fish. They need a lot of room to roam and can only survive in cooler climates. Habitat loss is threatening the Brown Bear.

The Polar Bear

The Polar Bear lives in areas surrounding the Arctic Ocean and associated seas. It is the world's largest carnivore species on land. It needs sea ice to rest on while fishing for food in cold ocean waters. A loss of sea ice is endangering the bear today.

The Woodland Caribou

The Woodland Caribou needs large amounts of boreal forest to survive, hide from predators, and find enough food. Since 1950, they have decreased in number by 50%. They are adapted to live in cool climates.

Polar bear

The Grey Wolf

The Grey Wolf, or timber wolf, was once the world's most widespread mammal. It is now found in a much smaller range because of human encroachment on its habitat. In many areas, the wolf is thriving; in others, it is nearing extinction.

The Giant Kangaroo Rat

The Giant Kangaroo Rat prefers desert-like environments, scurries in meadows, and digs holes in the ground, eating seeds and small insects. They can now only be found in California, living in 2% of their original habitat. They are threatened due to agricultural practices.

The Mississippi Gopher Frog

The Mississippi Gopher Frog loves southern pine forests and has strong hind feet to dig through and use other organisms' burrows for shelter. As of March, 2008, there were only an estimated 100 gopher frogs left in the wild.
